

BELIEF NETWORKS

CHAPTER 15.1–2

Outline

- ◇ Conditional independence
- ◇ Bayesian networks: syntax and semantics
- ◇ Exact inference
- ◇ Approximate inference

Independence

Two random variables A B are (absolutely) independent iff

$$P(A|B) = P(A)$$

$$\text{or } P(A, B) = P(A|B)P(B) = P(A)P(B)$$

e.g., A and B are two coin tosses

If n Boolean variables are independent, the full joint is

$$\mathbf{P}(X_1, \dots, X_n) = \prod_i \mathbf{P}(X_i)$$

hence can be specified by just n numbers

Absolute independence is a very strong requirement, seldom met

Conditional independence

Consider the dentist problem with three random variables:

Toothache, *Cavity*, *Catch* (steel probe catches in my tooth)

The full joint distribution has $2^3 - 1 = 7$ independent entries

If I have a cavity, the probability that the probe catches in it depends on whether I have a toothache:

(1) $P(\textit{Catch}|\textit{Toothache}, \textit{Cavity}) = P(\textit{Catch}|\textit{Cavity})$
i.e., *Catch* is conditionally independent of *Toothache* given *Cavity*

The same independence holds if I haven't got a cavity:

(2) $P(\textit{Catch}|\textit{Toothache}, \neg \textit{Cavity}) = P(\textit{Catch}|\neg \textit{Cavity})$

Conditional independence contd.

Equivalent statements to (1)

$$(1a) P(\textit{Toothache}|\textit{Catch}, \textit{Cavity}) = P(\textit{Toothache}|\textit{Cavity})$$

$$(1b) P(\textit{Toothache}, \textit{Catch}|\textit{Cavity}) = P(\textit{Toothache}|\textit{Cavity})$$

~Why??

Full joint distribution can now be written as

$$\begin{aligned} \mathbf{P}(\textit{Toothache}, \textit{Catch}, \textit{Cavity}) &= \mathbf{P}(\textit{Toothache}, \textit{Catch}|\textit{Cavity}) \\ &= \mathbf{P}(\textit{Toothache}|\textit{Cavity})\mathbf{P}(\textit{Catch}|\textit{Cavity})\mathbf{P}(\textit{Cavity}) \end{aligned}$$

i.e., $2 + 2 + 1 = 5$ independent numbers (equations 1 and 2)

Conditional independence contd.

Equivalent statements to (1)

$$(1a) P(\textit{Toothache}|\textit{Catch}, \textit{Cavity}) = P(\textit{Toothache}|\textit{Cavity})$$

$$\begin{aligned} P(\textit{Toothache}|\textit{Catch}, \textit{Cavity}) &= P(\textit{Catch}|\textit{Toothache}, \textit{Cavity})P(\textit{Toothache}|\textit{Cavity})/P(\textit{Catch}|\textit{Cavity}) \\ &= P(\textit{Catch}|\textit{Cavity})P(\textit{Toothache}|\textit{Cavity})/P(\textit{Catch}|\textit{Cavity}) \text{ (from 1a)} \\ &= P(\textit{Toothache}|\textit{Cavity}) \end{aligned}$$

$$(1b) P(\textit{Toothache}, \textit{Catch}|\textit{Cavity}) = P(\textit{Toothache}|\textit{Cavity})P(\textit{Catch}|\textit{Cavity})$$

Why??

$$\begin{aligned} P(\textit{Toothache}, \textit{Catch}|\textit{Cavity}) &= P(\textit{Toothache}|\textit{Catch}, \textit{Cavity})P(\textit{Catch}|\textit{Cavity}) \text{ (product rule)} \\ &= P(\textit{Toothache}|\textit{Cavity})P(\textit{Catch}|\textit{Cavity}) \text{ (from 1a)} \end{aligned}$$

Belief networks

A simple, graphical notation for conditional independence assumptions and hence for compact specification of full joint distributions

Syntax:

- a set of nodes, one per variable

- a directed, acyclic graph (link $\approx$ “directly influences”)

- a conditional distribution for each node given its parents:

$$\mathbf{P}(X_i | Parents(X_i))$$

In the simplest case, conditional distribution represented as a conditional probability table (CPT)
